These slides were originally designed by Silberschatz, Galvin and Gagne ©2013

## Scheduling Criteria

---

- **CPU utilization** – keep the CPU as busy as possible
  - **Throughput** – # of processes that complete their execution per time unit
  - **Turnaround time** – amount of time to execute a particular process
  - **Waiting time** – amount of time a process has been waiting in the ready queue
  - **Response time** – amount of time it takes from when a request was submitted until the **first response** is produced, not output (for time-sharing environment)
-

# Scheduling Algorithm Optimization Criteria

---

- **Maximize** CPU utilization
  - **Maximize** throughput
  - **Minimize** turnaround time
  - **Minimize** waiting time
  - **Minimize** response time
-

## First- Come, First-Served (FCFS)

<u>Process</u>	<u>Burst Time</u>
$P_1$	24
$P_2$	3
$P_3$	3

- Suppose that the processes arrive in the order:  $P_1, P_2, P_3$   
The Gantt Chart for the schedule is:

- Waiting time for  $P_1 = 0$ ;  $P_2 = 24$ ;  $P_3 = 27$
- Average waiting time:  $(0 + 24 + 27)/3 = 17$

## FCFS (Cont.)

Suppose that the processes arrive in the order:

$P_2, P_3, P_1$

- The Gantt chart for the schedule is:

- Waiting time for  $P_1 = 6$ ;  $P_2 = 0$ ;  $P_3 = 3$
- Average waiting time:  $(6 + 0 + 3)/3 = 3$
- Much better than previous case
- Convoy effect** - short process behind long process

## Shortest-Job-First (SJF)

---

- Associate with each process the length of its next **CPU burst**
  - Use these lengths to schedule the process with the **shortest time**
- SJF is optimal – gives minimum average waiting time for a given set of processes
  - The difficulty is **knowing the length** of the next CPU request

## Example of SJF

<u>Process</u>	<u>Burst Time</u>
$P_1$	6
$P_2$	8
$P_3$	7
$P_4$	3

- SJF scheduling chart

- Average waiting time =  $(3 + 16 + 9 + 0) / 4 = 7$

## Example of Shortest-remaining-time-first

- Now we add the concepts of varying arrival times and **preemption** to the analysis

<u>Process</u>	<u>Arrival Time</u>	<u>Burst Time</u>
$P_1$	0	8
$P_2$	1	4
$P_3$	2	9
$P_4$	3	5

- Preemptive* SJF Gantt Chart

- Average waiting time =  $[(10-1)+(1-1)+(17-2)+(5-3)]/4 = 26/4 =$   
**6.5 msec**

## Priority Scheduling

---

- A priority number (integer) is associated with each process
  - The CPU is allocated to the process with the highest priority (**smallest integer  $\equiv$  highest priority**)
    - Preemptive
    - Non-preemptive
  - Problem  $\equiv$  **Starvation** – low priority processes may never execute
  - Solution  $\equiv$  **Aging** – as time progresses **increase** the priority of the process
-

## Example of Priority Scheduling

<u>Process</u>	<u>Burst Time</u>	<u>Priority</u>
$P_1$	10	3
$P_2$	1	1
$P_3$	2	4
$P_4$	1	5
$P_5$	5	2

- Priority scheduling Gantt Chart

- Average waiting time = **8.2 msec**

## Round Robin (RR)

---

- Each process gets a small unit of CPU time (**time quantum  $q$** ), usually 10-100 milliseconds.
  - After this time has elapsed, the process is **preempted** and added to the end of the ready queue.
  - If there are  $n$  processes in the ready queue and the time quantum is  $q$ , then each process gets  **$1/n$**  of the CPU time in chunks of at most  **$q$  time units at once**. No process waits more than  **$(n-1)q$**  time units.
-

## Round Robin (RR)

---

- Timer interrupts every quantum to schedule next process
- Performance
  - $q$  large  $\Rightarrow$  FCFS
  - $q$  small  $\Rightarrow q$  must be large with respect to context switch, otherwise overhead is too high

## Example of RR with Time Quantum = 4

<u>Process</u>	<u>Burst Time</u>
$P_1$	24
$P_2$	3
$P_3$	3

- The Gantt chart is:

- Typically, higher average turnaround than SJF, but better **response**
- $q$  should be large compared to **context switch** time
- $q$  usually 10ms to 100ms, context switch < 10 usec
